Preface and Acknowledgements

The natural resource bank is gradually being drawn down. This book scrutinises the underlying causes of the degradation of natural resources. In this regard, it develops a new framework of sustainability in the case of the usage and management of natural resources by incorporating the idea of human sociality. Human sociality implies that humans are social beings, who behave in a reciprocal manner. As nature provides numerous benefits to human beings, they are naturally inclined to conserve and protect nature in return. Therefore, nature and human beings have a mutually beneficial relationship. This relationship, however, becomes distorted in a market economy.

The alternative framework emphasises the revitalisation of the symbiotic relations in order to progress toward a sustainable transformative pathway that can ensure the well-being of both nature and human beings by ensuring sustainable governance of natural resources. The framework thus entails that the well-being of human beings and nature must go side by side because one without the other is certainly not a viable option. Simultaneously, it considers the necessity of recognising political economy factors to pinpoint the root causes of natural resource degradation. Overall, the necessary condition is the revitalisation of mutual relations between human beings and nature while the sufficient condition is captured in terms of the nature of institutions and political settlement.

Specifically, the book examines biodiversity resources, water resources and climate change—the three most pressing issues in the realm of the current natural resource governance regime in the context of a developing country. It demonstrates, through theoretical and empirical analyses, that natural resources have been exploited beyond sustainable limits due to the commodification process, the existence of fragile institutions and unequal power-sharing arrangements. This results in the dissipation of natural resource rent, leading to the degradation of biodiversity resources, depletion and inequitable distribution of water resources, climate change as well as unsustainable development of the economy. Such degradation also steers intergenerational injustice because the younger generation of today is likely to suffer more in the future than their older counterparts.

The book relates to the COVID-19 pandemic, as there is a direct link between the pandemic and the destruction of nature. The 2030 Agenda for Sustainable Development with its biodiversity, water, climate change and other environment-related goals and targets is even more important today in the face of the pandemic, which has reinforced the need to protect biodiversity, ensure water security and halt climate change. In the light of the pandemic and its effects, accordingly, the book scrutinises the challenges of governing biodiversity, water and climate change.

Overall, the book offers important insights for academics and researchers specifically interested in the field of development studies who wish to gain a deeper understanding of sustainable natural resource governance, specifically in the context of developing countries. For policymakers and policy advocates, the book serves as a groundwork by providing pertinent contents in outlining the justification for policy objectives concerning biodiversity, water resources and climate change.

The authors would like to thank *Unnayan Onneshan*—an independent research think tank in Bangladesh—for providing support to conduct several research projects down the years to help build the foundation to plan and write this book. A significant amount of data for empirical analysis in this book was also collected under several research projects of this organisation. In line with that, the authors express gratitude to the researchers, Jayanta Kumar Basak, Mohammed Abdul Baten, Md Humayain Kabir, Tahera Akter, among others as well as the respondents who participated in those research. In addition, the authors would like to thank Azmol Hossain, Coordinator, and Mamun-ur-Rashid, Community Researcher, who also provided their support in conducting the studies.

Furthermore, the authors also express their gratitude to the anonymous reviewer(s) for their valuable insights for the development of the book. The authors' special thanks go to Assistant Prof. Md. Zahidur Rahman of Bangladesh University of Professionals, Dhaka, Bangladesh, for going through the first draft of the manuscript, which helped them in revising the chapters thoroughly. Last, but not least, the authors are grateful to their family members for their unwavering support throughout the journey in writing this book.

The authors are solely responsible for any errors, inadequacies and omissions that may still remain in the book even after a thorough review and proofreading. The authors will certainly address those in the next edition.

About the Authors

Rashed Al Mahmud Titumir is a Professor of Economics at the Department of Development Studies, University of Dhaka, Bangladesh and is currently holding the charge of the Chairman of the Department. He is the Founder-Chairperson of *Unnayan Onneshan*—a Dhaka based multidisciplinary think-tank, Vice Chairperson of IUCN Asia Regional Members Committee and Chairperson of IUCN National Committee of Bangladesh. His latest books are: *Fiscal and Monetary Policies in Developing Countries: State, Citizenship and Transformation* (Routledge); *State Building and Social Policies in Developing Countries: The Political Economy of Development* (Routledge); *Why Agriculture Productivity Falls: The Political Economy of Agrarian Transition in Developing Countries* (Purdue University Press); and *Numbers and Narratives in Bangladesh's Economic Development* (Palgrave Macmillan). He edited *Sundarbans and Its Ecosystem Services: Traditional Knowledge, Customary Sustainable Use and Community Based Innovation* (Palgrave Macmillan) and co-edited *COVID-19 and Bangladesh: Response, Rights and Resilience* (University Press Ltd).

Tanjila Afrin is an Assistant Professor at the Department of Development Studies, Bangladesh University of Professionals, Bangladesh. Her research focuses on the political economy of natural resource governance, environment and development, biodiversity conservation, climate change, poverty and inequality, livelihoods and governance.

Mohammad Saeed Islam is an Assistant Professor at the Department of Development Studies, Bangladesh University of Professionals, Bangladesh. His areas of research interest are environmental and resource economics, water economics and policy, environmental protest, agriculture and rural development, poverty and inequality and welfare economics.

Chapter 1

Setting the Context

1.1 Introduction

The worldwide concerns for deforestation, degraded soil, polluted air, declined water, endangered species and climate change are all well-meaning. Yet the causes, effects and solutions warrant meticulous scrutiny. The concerns have heightened in the face of the COVID-19 pandemic, as there is a direct linkage between nature's destruction and the outbreak of disease. It is imperative to protect nature by halting natural resource degradation to prevent future pandemics. In this backdrop, the book focuses on natural resource governance mechanisms illustrated with cases of biodiversity, water resources and climate change to identify the underlying causes of resource degradation, especially in the context of developing countries. It also attempts to bring forth a new understanding regarding the usage, management and conservation of natural resources in a sustainable manner.

The broad concerns that arise in the contemporary era are to (a) conserve nature in all its forms and functions and (b) create an equitable home and achieve a high standard of living for people on this planet without destabilising critical planetary processes (O'Neill et al., 2018; WWF, 2016). These dual challenges are also delineated in the United Nations' 2030 agenda for sustainable development. The Sustainable Development Goals (SDGs)—17 in total—under the agenda include several goals (Goals 6, 13, 14 and 15) which focus on nature and the environment directly (Elder & Olsen, 2019; Scharlemann et al., 2020), while other goals have indirect environmental implications as well.

However, specific targets to protect climate and biodiversity (under Goals 13, 14 and 15) are completely off track (Nature, 2020). Despite a temporary drop in carbon dioxide emissions due to the pandemic, the world is still heading for a temperature rise of more than 3 °C this century. This goes far beyond the Paris Agreement goals of keeping global warming below 2 °C and aiming for 1.5 °C (UNEP, 2020). Simultaneously, around 25% of biodiverse species on an average are threatened indicating that around 1 million species have already faced extinction (IPBES, 2019). Ensuring access to clean water (under Goal 6) also remains a major challenge. The

goal itself recognises that managing water sustainably goes beyond simply providing clean water to address broader issues such as water quality and watershed management, water scarcity and usage efficiency and restoration of water-related ecosystems (Dahan & Kashiwase, 2016). Essentially, the problems in the realm of biodiversity, water or climate are more acute in the context of developing countries due to the context-specific dynamics of resource governance. Moreover, there is also a paucity of studies in understanding the dynamics in that specific context. The book, accordingly, draws on the empirical evidence of a developing country—in this case Bangladesh—to highlight the complexity of issues.

The mainstream theories and policy options under the neoliberal regime primarily follow the market-centric approach to deal with the problems of natural resource degradation. The approach clearly suggests that the market is the best possible mechanism to allocate and distribute resources efficiently through a voluntary exchange, based on Pareto optimality arguments (Arrow et al., 1996; Freeman III et al., 2014; Pearce, 1991; Pearce et al., 1989; Stavins, 1989, 2011; Tietenberg, 1990; Zhang, 2013).

The assumption of voluntary exchange, however, does not always fit well with the real world, and the arguments on efficiency are not viable. The heterogeneity of ownership of natural resources causes the scope of inefficient consumption and overexploitation, which results in ‘market failure’ (see Chap. 2 for details). Thus, the continuous degradation of natural resources could not be stopped. Moreover, the market-centric approach ignores the factors related to political economy, which are the key forces that cause the failure of market mechanisms in transitional economies (Broad, 1995; Clark & York, 2012) and politics, in particular, can affect the exploitation of natural resources (Collier, 2010; López & Toman, 2006). Recent literatures recognise that a solution can be arrived at through the revitalisation of mutual relationships between human beings and nature (Díaz et al., 2015; Gu & Subramanian, 2012; Ichikawa, 2012). It is, however, yet to examine the actual implications of this understanding in resource governance regime in general and in developing countries in particular.

The book tries to contribute to this arena of resources governance regime by formulating a new framework pivoted around the concept of ‘human sociality’. The framework puts together variables such as institutions, power, political settlement along with human sociality into the alternative resource governance framework that helps understand the pitfalls in the mainstream governance framework to ensure a sustained relationship between human beings and nature. Overall, the book firstly scrutinises the market-centric perspectives and, secondly, combines political economy questions and human sociality that are usually overlooked in the discussions of the current governance framework. It ultimately develops an alternative framework to examine the reasons behind the degradation of natural resources and to offer viable and sustainable solutions to the problem.

The empirical analysis of the book demonstrates that in developing countries—as evident in Bangladesh—natural resources have been exploited beyond the sustainable limit due to structural rigidities, embedded in and reproduced by fragile institutions and unequal power-sharing arrangements under a market-centric economy. These

countries are also bearing a larger share of the burden emerging from climate change as compared to developed countries due to the factors pertaining to the international political economy. Therefore, in order to reverse the condition, it is important to recognise the inherent values of nature going beyond its narrow conceptualisation through a market-centric lens. This would ultimately ensure the well-being of nature and human beings simultaneously.

1.2 Biodiversity Resources

The loss of biodiversity, both at the regional and global levels, is quite evident. The Living Planet Index (LPI) of 2020 shows that between 1970 and 2016, the planet lost 68% of its biodiversity (WWF, 2020). Previous assessments also showed a persistent downward trend across different periods of time (e.g., LPI of 2018: 60% between 1970 and 2014, LPI of 2016: 58% between 1970 and 2012 and LPI of 2014: 52% between 1970 and 2010) (WWF, 2014, 2016, 2018). It implies that the rate of loss has also increased over the years. Moreover, the trend of biodiversity populations under various ecosystems exhibits a decline, and the greatest losses can be observed in the freshwater environment, followed by the terrestrial ecosystem (Table 1.1).

Additionally, the degrading trend in biodiversity varies from one region to the other (Table 1.2). The highest rate of degradation (94%) has been observed in Latin America and the Caribbean. The Asia Pacific region is in the third position, losing almost half of its total biodiversity over the same timeframe. Thus, differences are acute in the abundance of biodiversity resources across regions, with the largest decline being in tropical areas.

Table 1.1 Trend in biodiversity based on LPI 2016

Types of LPI	Trend in population (between 1970 and 2012) (%)	Annual decline (%)
Terrestrial	– 38	1.1
Freshwater	– 81	3.9
Marine	– 36	1.0

Source WWF (2016)
