# Acknowledgements

This document is my dissertation titled “Design, Development and Sensemaking of Human-Robot Interaction in Care Settings,” and describes my research activities between 2018 and 2022 at the Institute for Information Systems and New Media, University of Siegen. It was influenced by my involvement as a student in the research cooperation between the university and a care home in the period from 2015 to 2018.

Although my name appears on the front page of this document, it could not have been accomplished without the cooperation and assistance of others. I am grateful to everyone who helped me reach this point. I believe this is a shared achievement. I received assistance in various areas for an extended period, and it is impossible to name everyone who helped me along the way because there were so many of you. As a result, I will refrain from using names and hope that each of you understands that I am referring to you. This support extended beyond immediate assistance with my research; it included meaningful conversations, feelings of connection, and moments of discovery. I’m sure I received assistance that I was not even aware of, people opening doors or helping me to overcome obstacles I was not aware existed. The assistance I received allowed me to create this work, and it would not have been possible without you.

I would like to express my gratitude to all the participants and institutions who granted me access to their resources. Special thanks to those individuals I have pseudonymized, you were critical to the success of this project. I understand that I have made significant demands at times, and I appreciate the effort you have put in to make our work possible. Your insights have been invaluable, and I am honored to have been a part of your lives. I acknowledge that this is not the norm.

I recognize that this was only achievable due to your efforts. You made me see, and I am grateful for that.

Although I am profoundly thankful, I think I also need to express regret. This thesis has consumed a significant amount of my time and energy. As a result, I might have neglected personal relationships and missed important events, conversations, and visits. I deeply appreciate the patience and understanding shown by my friends and family during this period and know that I was not the only one that has been investing time and nerves to create this work. Thank you for enabling this work.

---

# Abstract

Western societies' demographic shift toward an older population has been a long-term trend. Consequently, the number of people in need of care services has increased. The number of people employed in the care sector is not increasing at the same rate. As a result, the existing workforce and the system are under strain. At the same time, technology has advanced rapidly. Social robots are one of these innovations that are gradually becoming a part of everyday life. Social robots' new functional and interactive capabilities make them relevant in care settings.

This dissertation investigates the potential of a social robot in care homes to assist the workforce and contribute to the well-being of residents. Several studies are presented that use a socio-informatics approach to make sense of social robots in care homes. They investigate how residents and caregivers interact with social robots, analyze and shape their appropriation, and how informed decisions can be made for the development of the software and hardware of the robots. The findings indicate that social robots can play a role in care homes. However, they can only assist and not replace care workers. They broaden the possibilities for social care workers and, when integrated into daily work practices, can provide small breaks. They can also have a positive impact on residents by motivating them to engage in cognitive and physical training.

We chose to explore the field using a participatory approach to design the robot's functionalities. Research and development was done within care homes together with the people working and living there. The findings aim to contribute to the HCI and HRI community by demonstrating the benefits, challenges, and ambiguities of long-term use of social robots in care homes.

# List of Publications

This dissertation consists of an accumulation of publications that have been accepted and published. Chapter 4 corresponds to P1, Chap. 5 to P2, Chap. 6 to P3, Chap. 7 to P4, Chap. 8 to P5, and Chap. 9 to P6. The list of all publications is in Table 1 below. The publications are a shared result. I thank all my co-authors for the collaboration on these.

# Part I

## Foundations

The first section of the dissertation presents its foundations and context. Chapter 1, the introduction, explains the subject and my own motivation, as well as its limitations. Chapter 2 places the dissertation's work in the context of related work and demonstrates the need for change within the sector, and explains why social robots can contribute to this change. In Chap. 4, the last chapter of this first part I present the methodology of this work, how I approached the field and learned from it and reflect on the experiences in the field.

## 1.1 Problem Definition

Today we can say with certainty that the care system in Western societies, and specifically in Germany, is under pressure. In the coming decade this pressure is likely to increase, not decrease. The reasons for this trend are manifold, but the main driving force of this development is demographic change. German society is growing older and has fewer younger people. The number of people in Germany older than 80 years is predicted to grow from 6.2 million in 2022 to 8.9–10.5 million in 2050. By comparison, in 1970 Germany had 1.15 million people over 80 years old [54, 117]. Another reason is that the number of people working in care is not growing at the same pace; in fact, many positions remain unfilled [19]. In summary, the number of people in need of care grows while the number of people working in care does not, resulting in a shortage of workers and a need for assistance. Far from being a surprising development, this has been projected since decades past, but today we have a clearer picture of it.

This raises a question: How can care work be assisted, and can technology play a role in this assistance? In this work, we look at social robots and how they can (or cannot) be of assistance in the care field. Social robots in care settings are not new; they existed long before this work was written and appear in a range of topics including nutrition, entertainment, loneliness or hygiene. The global research community has worked intensively on social robots in care settings as it is a common vision to help the care sector with robots. The general idea is to assist the care sector with robotic systems in order to relieve the work force, something that previously was done in the industrial sector [112]. In the industrial sector, it is nowadays not uncommon to see a variety of robots working together to create a product, sometimes fully automated. Human workers do not have the same jobs as they used to in places
