### 1.1 Introduction

The foundational principles and ideas behind BCT have roots dating back to the 1980s. Digital signatures on documents were made possible in 1991 by the use of a chain of information as an electronic record. By the early 2000s, this concept merged with electronic cash, leading to the creation of Bitcoin, the pioneering blockchain application widely accepted across sectors. Bitcoin allowed direct transactions without intermediaries, initially providing user anonymity, though their transactions became visible. The term "pseudo-anonymous" was coined emphasizing the need for trust mechanisms in an environment where user identification was not straightforward. Before blockchain, trust was facilitated by intermediaries [1, 2].

In the absence of trusted intermediaries, BCT is recognized for its four key characteristics: ledger, security, shared, and distributed. These attributes create trust among users, even without their explicit knowledge [3, 4]. Over the past decade, information technology disruptions have reshaped industries and businesses, prompting questions about sustainability. Sustainability, in this context, entails reducing financial saving costs, the cost of mistrust, disruptions from other fintech companies, and eliminating the need for intermediaries [4, 5]. Nevertheless these difficulties, new business paradigms have been brought about by the internet, with blockchain being a widely used application in the banking industry following the global financial crisis of 2008. Paired with artificial intelligence, IoT, and virtual reality, blockchain's decentralization, transparency, and immutability contribute to trust and security in network [6]. The application

of blockchain extends beyond finance promising radical changes in telecommunications, healthcare, music and entertainment, energy, real estate, insurance, and other sectors. This chapter presents a complete introduction of BCT, including its various uses and future research directions. It illuminates the function and features of blockchain in numerous businesses uncovering hidden areas that provide opportunity to address obstacles.

## 1.2 The Evolution of Blockchain

The foundational ideas and principles of BCT have been in existence since the 1980s. In 1982, Chaum published his dissertation thesis, which was the first to explicitly suggest a system similar to blockchain [7]. In 1991, an electronic record for digitally signed documents was created using a chain of blocks that was cryptographically secured, as later reported by Haber and Stornetta [8]. Merkle trees were included into this encryption method [9]. In 1998, Szabo developed the idea for “bit gold,” a decentralized system of electronic money [10]. In the early 2000s, this concept was integrated with electronic cash eventually leading to the creation of Bitcoin. When Nakamoto first introduced Bitcoin in 2008, it was a peer-to-peer (P2P) network that offered electronic currency [11]. Additionally, this year saw the introduction of the term “blockchain,” referring to the distributed ledger technology that enables Bitcoin transactions [12]. Bitcoin, being the first widely accepted blockchain application, allowed users to engage in direct transactions without the need for third-party mediation. Unlike previous electronic cash schemes, Bitcoin gained widespread acclaim due to its decentralized nature providing users with control over their electronic cash without a single point of failure. Bitcoin initially allowed users to remain unidentified, but their transactions were visible resulting in pseudo-anonymous accounts. The need for trust mechanisms in an environment where user identification is not straightforward is becoming crucial. Prior to BCT, trust relied on intermediaries.

In 2013, Ethereum was introduced by Buterin through his whitepaper. Crowd sourcing was used to support Ethereum’s development in 2014, and on July 30, 2015, the Ethereum network was operational. Ethereum was the first project to provide Blockchain 2.0, setting itself apart from other endeavors that were only concerned with producing altcoins that resembled Bitcoin. In contrast to these initiatives, Ethereum used distributed apps on its blockchain to enable connections without trust. Ethereum was created for distributed data storage and smart contracts, which are small computer programs, whereas Bitcoin was intended for a distributed ledger.

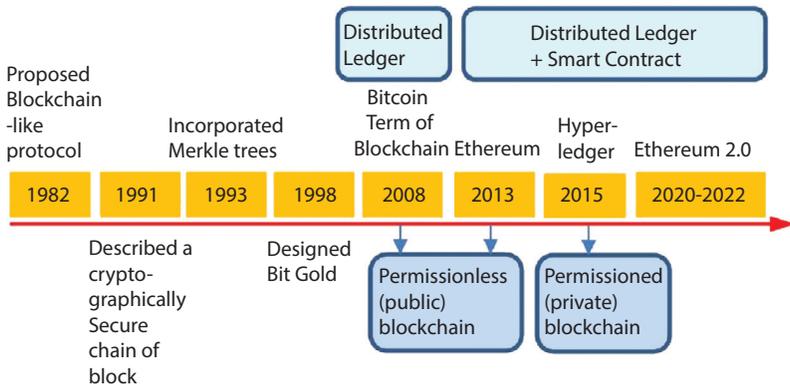

Figure 1.1 History of blockchain adopted from Guo and Yu [13].

Over the course of three phases, the Ethereum 2.0 upgrade from 2020 to 2022 sought to improve the network’s speed, scalability, efficiency, and security [13].

In 2015, the Linux Foundation unveiled the Hyperledger project, an open-source software initiative for blockchains. Geared toward constructing enterprise blockchains, Hyperledger blockchain frameworks differed from Bitcoin and Ethereum. Hyperledger encompasses eight blockchain frameworks (Hyperledger Besu, Hyperledger Fabric, Hyperledger Indy, Hyperledger Sawtooth, Hyperledger Burrow, Hyperledger Iroha, Hyperledger Grid, and Hyperledger Labs), five tools (Hyperledger Avalon, Hyperledger Cactus, Hyperledger Caliper, Hyperledger Cello, and Hyperledger Explorer), and four libraries (Hyperledger Aries, Hyperledger Quilt, Hyperledger Transact, and Hyperledger URSA) [14]. The history of blockchain, as depicted in Figure 1.1, showcases Bitcoin and Ethereum as public blockchains allowing anyone to participate in their networks (permission less blockchains). In contrast, the diverse Hyperledger blockchain networks are private blockchains necessitating participant verification before network entry (permissioned blockchains).

### 1.2.1 Development of Blockchain Generation

The progression of BCT can be classified into three clear phases as follows: Blockchain 1.0, focusing on digital currency; Blockchain 2.0, centered around the digital economy; and Blockchain 3.0, aimed at shaping the digital society [15–17].

- **Blockchain 1.0—Digital Currency:** The first phase of BCT, known as Blockchain 1.0, focuses on fundamental components, including public ledger, hashing, and mining. This phase comprises the underlying protocol, transaction enablement, and the introduction of digital currencies such as Bitcoin. Bitcoin distinguishes out as a real implementation that predates theoretical talks [18]. Its principal features are much lower transaction costs for online transactions, greater anonymity compared to credit cards through pseudonymous accounts, and a decentralized architecture that protects against inflation by utilizing cryptography to keep a relatively constant money supply [19].
- **Blockchain 2.0—Digital Economy:** Blockchain 2.0 encompasses an extensive array of economic and financial applications beyond basic payments and transactions. This phase includes traditional banking products, complex financial market instruments, such as stocks and derivatives, legal documents like titles and contracts, as well as services like loans and mortgages. Notable applications involve payment clearing systems, bank credit information systems, and the emergence of smart contracts. Smart contracts, executed automatically upon meeting predefined conditions, have found applications in various fields, including leasing cars [20]. Platforms, like Ethereum, while prominent, face security challenges that developers aim to address using tools like Oyente [21].
- **Blockchain 3.0—Digital Society:** Blockchain 3.0 ushers in applications that extend beyond economic realms, spanning areas such as art, health, science, identity, governance, education, public goods, culture, and communication. Noteworthy applications include the advancement of smart cities, integrating facets like smart governance, mobility, living standards, resource management, citizen engagement, and economic activities [22]. The Internet of Things (IoT) emerges as a pivotal platform for e-business, facilitated by blockchain's support for P2P trade and smart contracts, enabling transactions involving smart property and paid data [23, 24]. In the chemical industry context, blockchain facilitates machine-to-machine (M2M) interactions and establishes M2M electricity markets [25]. Additionally, the technology enhances large-scale data management in

electronic medical records (EMR) systems ensuring interoperability, accessibility, and auditability [26]. Digital identity, empowered by blockchain, holds the potential to transform lives, especially for the unbanked population, by providing access to financial services and regulatory compliance. Additionally, the BCT introduces opportunities to redesign reputation systems in the cyber world, addressing vulnerabilities associated with fraud rating [26].

### 1.3 Exploring the Peculiar Characteristics of Blockchain

BCT represents a cutting-edge approach with the potential to revolutionize equality, accountability, decentralization, and transparency on the internet [27]. Rooted in an egalitarian philosophy, its objective is to establish a decentralized structure for P2P transactions promoting trust and circumventing intermediaries. Blockchain utilizes a secure and transparent technology to facilitate data storage and transmission among users obviating the necessity for a central control point [28]. As expressed by Rodrigues *et al.* [29], blockchain redistributes control from centralized entities to users in a decentralized and transparent fashion.

- **Decentralization:** In traditional centralized systems, every transaction must be validated by a central authority, like a central bank, which requires confidence. However, decentralization seeks to overcome the trust issue by adding a decentralized P2P blockchain architecture. Unlike centralized systems, in which transactions need authentication from a central agency, blockchain allows any two peers to conduct transactions without such authentication [30]. Blockchain uses a variety of consensus processes to address trust problems providing benefits such as lower server costs and decreased performance overheads at the central server. It is worth noting that, despite these advantages, some trade-offs remain, notably in consensus techniques, like Proof of Work (PoW) used in Bitcoin and Ethereum, where server and energy costs are greater, and speed may suffer [28].
- **Persistence:** Blockchain establishes an infrastructure that facilitates the objective measurement of truth and validates the
