Acknowledgments

Most people who met me in the last four years know that neither starting, nor pursuing or finishing this thesis was an easy task. Writing these words means that what appeared so terribly unreachable has actually been achieved. Persevering through hard times has been made possible by the passion I had and still have for the subject of my research and, more generally, for the questions related to the marine environment and sustainability upon which it touches. But even more, what kept me going were the people I was blessed to have around me who trusted my abilities whenever I doubted them.

Amongst such people are first of all the members of my family. I want to thank you, Maman and Roger for your support and empathy, Tony for your availability now and always, Coline for your unusual wisdom, which often reminds me of what really matters, as well as my Granny and Mariette, who unfortunately did not get to see this publication. As blood is not all that matters, I would like to extend these special thanks to Alexia, for your longstanding friendship: you definitely made it in the family group by now. As for the Strasbourg quartet, Caroline, Jean-Sébastien, Suzanne and Noémi, you offered me some of the greatest joys of these last years as well as structured weekends from which I always came more productive, if not always rested. Last but not least, in this first round of naming and expressing gratitude, I would like to thank you Garth for the understanding—and useful—ear with which you listened to my substantive questions and to footnotes-related frustrations.

Then, my appreciation goes to my friends, all over Europe, for their support at various stages of this adventure. Amongst many others, I would like to thank by name Mike, Hannah and Frank for their precious pieces of advice at an early stage, as well as my office colleagues in Hamburg, Lief and Lina for their positive and supportive attitude. A special thanks to Sarah for generously reading a full draft and providing me with valuable comments and encouragements. Then, my gratitude to Tess, Maja, Johannes and Ole for the refreshing off-time moments we shared in Hamburg. In Cambridge, through good work and hard times, my appreciative thoughts go to Mariangela, David, Laura and Pia for their friendship and the great memories we shared.

vi Acknowledgments

After these personal remarks, I would like to express my more formal thanks to the International Max Planck Research School for Maritime Affairs program that financed my scholarship and provided me with a comfortable situation, to Professor Doris König (Bucerius Law School, Hamburg) who acted as my supervisor and to Barbara Krah-Schröder, our program coordinator, who successfully dealt with my academic moods, administrative problems and serious doubts. Needless to say, I would not be writing the words prefacing this book had it not been for her patient and understanding presence.

Finally, a last group I wish to thank is composed of the many interesting people who listened to the development of my research, intellectually challenged me, and offered me a time 'off-thesis' with shorter-time professional gratification or achievements. In this category, I would in particular like to express my gratitude to the two academics who, by teaching me respectively the law of the sea and international environmental law at the University of Edinburgh, sent me on the path that led to this dissertation: these people are James Harrison, who provided me with some very much appreciated support in the difficult early months of settling in the Ph.D. routine, and Alan Boyle, who showed interest in my progress throughout these years. As for the time I spent at the FAO Fisheries and Aquaculture Department, it was not only an opportunity to undertake fundamental research for my thesis but also a chance to discover other issues in the fisheries field, in particular those related to small-scale fisheries—I would like to thank Rolf Willmann, Nicole Franz, Gail Lugten, Carlos Fuentevilla, Monica Barone and Johanne Fischer for their warm welcome.

To get started with the serious part now, a Babylonian proverb has it that the gods do not deduct from a (wo)man's allotted span the hours spent fishing; I do sincerely hope that they extend such generosity to the years spent writing a thesis about this activity!

Chapter 1 Introduction

"[T]he oceans of the world continue to suffer from the survival of the philosophy of the commons. Maritime nations still respond automatically to the shibboleth of the 'freedom of the seas.' Professing to believe in the 'inexhaustible resources of the oceans,' they bring species after species of fish and whales closer to extinction."

(G. Hardin, 'The Tragedy of the Commons' (1968) 3859 Science 1243, 1245)

The current situation of many commercially-exploited fish species is worrying with nearly 30 % of all stocks around the globe qualifying as overfished. In particular, the biomass of big predatory species, such as tunas, is severely reduced. As for collapsed stocks, for instance the cod in the Northwest Atlantic, they will need several decades to recover from overexploitation. Overfishing, caused by excessive—and yet often disregarded—quotas, driven by fleet overcapacity and aggravated by illegal, unreported and unregulated (IUU) fishing, dangerously depletes stocks and threatens to drive some species to extinction. The resource management regimes in charge have consequently been widely criticized; the institutions involved, their interactions and balance sheets are questioned, but with no easy one-size-fits-all solution in sight.

The current fishing crisis is a serious challenge on the social, economic and of course ecological levels, particularly since "nearly two-thirds of humanity inhabit coastal areas and depend on coastal and marine environments for their livelihoods." The fisheries and aquaculture sector employed, in 2012, more than 58 million people directly and several hundred millions if ancillary (post-harvest) jobs and dependents are counted. A billion people's protein intake mainly comes

2 1 Introduction

from fish⁵, which represents more than 15 % of the total animal protein consumed in the world.⁶ Also, "the estimated annual landed value of fish globally is around USD 90 billion", ⁷ that of fish and fishery products exports nearly reached USD 130 billion in 2011, making it "[f]or developing countries [...] by far the most valuable of agricultural commodities [traded internationally]". ⁸ As for the ecological impact of bad management leading to stocks' depletion, the disappearance of one—or more—of an ecosystem's constituent parts has obvious consequences on the whole trophic chain and even on the physical components' equilibrium. ⁹

The fast-growing industry of aquaculture might appear to be the solution to the current fishing crisis. Undeniably, aquaculture is promising, but it also creates problems in relation to the sustainable management of wild fish stocks. This is particularly true if it has a farm-ranching component based on the fattening, in a controlled environment, of wild-caught juveniles. Nearly half of the fish products consumed nowadays comes from aquaculture sources. ¹⁰ It is hence impossible to discuss fisheries issues without looking at the effects of aquaculture on wild capture and at the implications of general conservation measures on such practices.

and Aquaculture' (Rome 2010) 6, 26). In 2010, 54.8 million people were engaged directly in fish production while it was estimated that the livelihoods of 660 to 820 million people depended upon it indirectly (FAO, 'The State of the World Fisheries and Aquaculture 2012' (n 1) 10, 41). In 2012, 58.3 million people were engaged directly in capture fisheries and aquaculture and 10 to 12 percent of the world's population depended on those sectors for their livelihood (FAO, 'The State of the World Fisheries and Aquaculture 2014' (n 1) 27, 31–32).

⁹N. Matz, Wege zur Koordinierung völkerrechtlicher Verträge: Völkervertragsrechtliche und institutionelle Ansätze (Springer 2005) 136. A well-known example is that of sea otters (see infra Chapter 4 A. II. 2.). Depletion can also lead to changes in the ecosystem balance (C. Mullon, P. Fréon and P. Curry 'The dynamics of collapse in world fisheries' (2006) 6 Fish and Fisheries 111, 112; J. B. C. Jackson and others, 'Historical overfishing and the recent collapse of coastal ecosystems' (2001) 293 Science 629; WWF, 'On the Brink - Mediterranean Bluefin Consequences of Collapse' http://assets.panda.org/downloads/ onthebrinktunacollapse.pdf accessed 4 July 2015, 3-4). The heavily fished seas also become mostly populated by smaller fishes, jellyfish and microbes (K. M. Gjerde, 'High Seas Fisheries Governance: Prospects and Challenges in the 21st Century' in D. Vidas and P. J. Schei (eds), The World Ocean in Globalisation: Climate Change, Sustainable Fisheries, Biodiversity, Shipping, Regional Issues (Martinus Nijhoff Publishers 2011) 224; P. A. Larkin, 'Concepts and issues in marine ecosystem management' (1996) 6 Reviews of Fish Biology and Fisheries 139, 152).

¹⁰ Nearly 46 % in 2008 as reported in FAO, 'The State of the World Fisheries and Aquaculture 2010' (n 4) 3, 18; 47 % in 2010 as reported in FAO, 'The State of the World Fisheries and Aquaculture 2012' (n 1) 26. Percentage reviewed down to 42.2 % for 2012 (FAO, 'The State of the World Fisheries and Aquaculture 2014' (n 1) 19).

1 Introduction 3

The purpose of the present study is to consider possible ways to attain sustainable and legal fishing, thus avoiding further depletion of stocks or even extinction of species. The adequacy of using the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) for commercially-exploited fish species will be assessed and the cooperation between relevant institutions examined. In particular, the recent partnership between the Food and Agriculture Organization (FAO) and CITES will be analyzed, as will be the role of regional fisheries management organizations (RFMOs) in relation to a listing of fish species under CITES.

The organizations studied here, the FAO, RFMOs and CITES, adopt different approaches to the protection of marine species. A regime focusing on conservation is indeed proposed by CITES while rather exploitation-oriented regimes are based on the FAO for global principles and on RFMOs for the practical management of resources. RFMOs are usually the entities with primary responsibility for the management of stocks and they attempt—with variable results—to implement, at the regional level, the goals of optimum but sustainable utilization of fisheries promoted by the FAO.

In the current context where some fish species are depleted and international trade is a major factor in the market for fish products, ¹¹ CITES, as a treaty regime regulating trade in endangered species, can be expected to play a beneficial role. Indeed, using the CITES structure to implement the FAO's main goal of sustainable fisheries as well as to provide an alternative or additional tool for fisheries matters when regional management proves inadequate is an attractive option. The same can be said of taking advantage of the RFMOs' and FAO's expertise to provide CITES with the best available scientific data and necessary technical information.

While a partnership between CITES and the FAO was undertaken already at the end of the 1990s, although informally at first, some concerns have been expressed about CITES' suitability regarding fisheries management. Highlighted as problematic were its lack of expertise in the marine field, its allegedly preservationist tendencies and the perceived threat it poses to RFMOs' mandates. The existence of a substantive overlap regarding the sustainable management of commercially-exploited and endangered fish species also appeared to be a major issue in the decision not to afford protection to certain fish species under CITES. However, such overlap does not necessarily mean that the institutions are or should be in confrontation. Cooperation has indeed the potential, under certain circumstances, to improve the situation and, more generally, is a practical way to face fragmentation of international law.

Two main concrete questions underlie this research: the first refers to whether CITES can and should be used for commercially-exploited fish species and the other examines whether the existing institutional cooperation is efficient. In addition to the practical contribution made by clarifying the value of using CITES and recommending ways to improve the system, this particular case-study provides an

¹¹ Sovacool (n 3) 98.

4 1 Introduction

interesting lens to approach wider international law issues. Indeed, finding ways to achieve effective governance of transboundary or global natural resources is central for the peaceful use of oceans and land. Furthermore, the role of science in advising decision-makers is a sensitive issue which deserves scrutiny and is similar in many regimes. Finally, the complex problem of fragmentation of international law is acute in various fields of environmental law, as in all rapidly developing areas of international regulations. This has been recognized in 2012 in *The Future We Want*, when the heads of states and other representatives declared: "[w]e encourage parties to MEAs [i.e. multilateral environmental agreements] to consider further measures, in these and other clusters, as appropriate, to promote policy coherence at all relevant levels, improve efficiency, reduce unnecessary overlap and duplication, and enhance coordination and cooperation among MEAs". 12 Hence, looking at successes—and failures—in regimes' cooperation and analyzing the causes and risks that fragmentation gives rise to are aspects of the present research that are transferrable to most legal regimes in need of increased coordination and coherency.

In order to determine ways to improve the conservation and management of fish stocks, it is important to start by identifying the problems which stocks of commercially-exploited fish species are facing. The overview chapter introduces the issue of stock depletion through the most recent statistics available, before briefly describing the causes of such problem and the impact of aquaculture on the general picture (Chapter 2: Fishing Crisis and Aquaculture). In the following section, the treaties and institutions dealing with these issues are presented (Chapter 3: Global and Regional Legal Regimes Dealing with Commercially-exploited Marine Species). Fragmentation, lack of political will, inadequate measures, poor implementation and enforcement are a few of the numerous institutional and structural challenges which permit and/or cause overfishing as well as IUU fishing; these issues ought to be examined in parallel with the characteristics of what would represent or could facilitate appropriate governance of fisheries (Chapter 4: Structural and Governance Issues).

In the fifth section of this research, the legality, adequacy and expected efficacy of the protection of commercially-exploited fish species under CITES are discussed (Chapter 5: Protection of Commercially-exploited Fish Species Under CITES). The cooperation of CITES with other institutions in the listing of commercially-exploited fish species is the topic of the following chapter: the several situations in which partnerships exist and/or are needed are presented, their frameworks, strengths and weaknesses analyzed and compared with some of CITES' other partnerships (Chapter 6: CITES Cooperation with Other Institutions in Relation to Commercially-exploited Fish Species).

Finally, a concluding part addresses the desirability of using CITES for commercially-exploited fish species under the current partnerships. It also provides

¹² The Future We Want – endorsed in UNGA Resolution A/RES/66/288 27 July 2012 (Document adopted at Rio + 20) §89.

1 Introduction 5

some recommendations as to the conditions under which CITES should be used for such species as well as to desirable changes both in the regime and in the collaborations (Chapters 7 and 8: Desirability of Using CITES and Recommendations).

The terminology 'commercially-exploited aquatic species' stems from the CITES-related activities of the FAO, but has not been formally defined. The gentlemen and ladies' agreement within CITES is to use the FAO understanding of the words, namely as a reference to all marine and freshwater fish and invertebrate species—mammals, birds, reptiles and plants are consequently excluded. This is wider than the ambit of the present research, which concentrates on marine species and tends to focus on fish (sharks included), with invertebrate used only as illustration of implementation aspects. The protection of marine mammals serves for comparison purposes. Hence the preferred wording will be 'commercially-exploited fish species' when referring to fish species only and 'commercially-exploited marine species' when referring to both marine fishes and mammals.

Part I Fishing Crisis, Regulations and Structural Issues

Chapter 2 Fishing Crisis and Aquaculture

Many stocks of commercially-exploited fishes are overexploited with collapse as a possible consequence, especially in the case of particularly vulnerable species. This is the overarching problem of today's fisheries. While the validity of the most alarming reports is questioned by some, the large majority of scientists agree that the current level of exploitation of many fisheries is not sustainable in the long-term² (A).

The problem of fish species' depletion is mostly caused by overfishing, IUU fishing and incidental by-catch.³ However, other factors such as habitat alteration⁴ or climatic variations have an important effect on the ability of stocks to replenish and thus on the level at which sustainable fishing can be set (B).

¹ On more vulnerable species, see W. W. L. Cheung and others, 'Intrinsic vulnerability in the global fish catch' (2007) 333 Marine Ecology Progress Series 1; J. A. Hutchings and J. D. Reynolds, 'Marine fish population collapses: consequences for recovery and extinction risk' (2004) 54 BioScience 297. Multiple examples of species extinction in marine species are provided in N. K. Dulvy, Y. Sadovy and J. D. Reynolds, 'Extinction vulnerability in marine populations' (2003) 4 Fish and Fisheries 25, 28–35.

² V. Christensen and others, 'Hundred-year decline of North Atlantic predatory fishes' (2003) 4 Fish and Fisheries 1; S. M. Garcia and C. Newton, 'Current situation, trends, and prospects in world capture fisheries' in E. K. Pikitch, D. D. Huppert and M. P. Sissenwine (eds), *Global Trends: Fisheries Management: Proceedings from the symposium held in Seattle, Washington, USA, June 14–16, 1994* (American Fisheries Society 1997); R. Hilborn and others, 'State of World Fisheries' (2003) 28 Annual Review of Environment and Resources 359; D. Pauly and others, 'Towards sustainability in world fisheries' (2002) 418 Nature 689; FAO, 'The State of the World Fisheries and Aquaculture' (Rome 2010) 8.

³ These are also the main factors contributing to collapse of stocks (D. Freestone, 'Problems of High Seas Governance' in D. Vidas and P. J. Schei (eds), *The World Ocean in Globalisation: Climate Change, Sustainable Fisheries, Biodiversity, Shipping, Regional Issues* (Martinus Nijhoff Publishers 2011) 110; C. Mullon, P. Fréon and P. Curry 'The dynamics of collapse in world fisheries' (2006) 6 Fish and Fisheries 111, 119; Pauly and others (n 2)).

⁴N. K. Dulvy and others, 'Methods of assessing extinction risk in marine fishes' (2004) 4 Fish and Fisheries 255, 256.

Aquaculture and farm-ranching are presented by some of their supporters as the solutions to the fishing crisis. These practices have clearly some potential as ersatz to wild-capture, but they also bring problems of their own, particularly with regard to catching juveniles as spawning stock and to the use of wild-caught fish as food for predatory aquaculture stocks (C).

A. State of Wild Stocks

I. Decreasing Stocks

1. Fishes: Statistics

Without fishing pressure, stocks benefit from a biological equilibrium level, as the number of juveniles of one generation recruited in the mature stock and the biomass growth balance the losses both in number and biomass caused by natural mortality.

Fishing represents an additional withdrawal factor, but it is still possible to keep stable stocks in the long term if the levels harvested are below or at the maximum sustainable yield (MSY).⁵ Indeed, after an sharp initial decrease, a stock that is exploited for the first time re-equilibrates at a new level, with fewer old individuals and more young ones which, all things being equal, have a faster growth rate.⁶ A cycle of faster growth of stocks is hence put in place by removing the older fish which grow only marginally. In some general models, it seems accepted that a decline of 50 % of the pre-exploited stock quantities represents a sustainable utilization level, therefore a desirable target.⁷

Nowadays, the amount of fish caught is in many cases over that equilibrium point "where withdrawals through catch are exactly replaced by natural additions". Statistical data such as the FAO State of World Fisheries and Aquaculture (SOFIA) reports non-sustainable fishing practices. According to the most recent edition, nearly 30 % of fish stocks are overexploited. Furthermore, 57 % of stocks are fully exploited and should consequently not be envisioned for expansion. This leaves only about 13 % of worldwide stocks which could produce more than their current level of exploitation, against 40 % in the mid-1970s. In contrast, the values
