Contents

List of Contributors, viii

Preface, xiii

Part 1 Investigating IBD in the 21st Century

- 1** Capsule endoscopy: do we need it? 1
Joel E D Mawdsley & Mark Appleyard
- 2** Pathology reports – pitfalls for the unwary, 5
Wilfred Weinstein
- 3** Non-invasive diagnosis and assessment, 8
Alex J Di Mambro, Ana Terlevich & Chris Probert
- 4** What is the best way to image perianal Crohn's disease? 11
Vikram A Sahni & Alison McLean
- 5** Surveillance colonoscopy in UC: alternatives and ways to improve outcome, 15
Mark Lust & William Connell
- 6** Abnormal liver tests – what should we do about them? 18
Richard Marley & Abid Suddle

Part 2 Medical Treatment: Making the Most of What We've Got

5-ASA drugs

- 7** Is monitoring necessary? 21
Rakesh Shah & Alastair Forbes
- 8** Do they have a role in Crohn's disease? 25
Vikrant Sibartie & Brian Feagan

Steroids

- 9** Steroids in Crohn's: are they obsolete? 28
David Rampton

Antibiotics for Crohn's disease

- 10** Antibiotics: which, when and for how long? 32
Alex Kent & Jean-Frédéric Colombel
- 11** *Mycobacterium avium paratuberculosis* in Crohn's disease: player or spectator? 36
Geoff Smith & Fergus Shanahan

Immunomodulators

- 12** TPMT testing: is it essential? 40
Azhar Ansari & Jeremy D Sanderson
- 13** 6-Mercaptopurine or azathioprine? 45
Dermot McGovern & Simon Travis
- 14** Thiopurines: how long should we use them for? 48
Alexandra Daley & Marc Lémann
- 15** Making the most of methotrexate, 51
Emma Greig, John Keohane & Brian Feagan
- 16** Cyclosporine: balancing risk and benefit, 55
Helena Deeney & Barney Hawthorne

Infliximab

- 17** Contraindications – absolute or relative? 59
Rakesh Chaudhary & Subrata Ghosh
- 18** How can we prevent tuberculosis? 63
Sasha Beresford & David Rampton
- 19** Dealing with infusion reactions, 67
Gert Van Assche, Séverine Vermeire & Paul Rutgeerts
- 20** Use in ulcerative colitis, 70
Sreedhar Subramanian & Jonathan Rhodes
- 21** Infliximab and surgery: health or hazard? 74
David Rampton

Nutritional therapy for Crohn's disease

- 22** Nutritional therapy for Crohn's disease: is it for adults? 77
Donald R Duerksen & Charles N Bernstein

Part 3 Medical Treatment: What's Round the Corner?

- 23** Trials and tribulations – interpreting clinical trials in IBD, 81
Elizabeth Carty & David Rampton
- 24** Genetics – clinical and therapeutic applications, 85
Mark Tremelling & Miles Parkes

- 25** Probiotics – separating science from snakeoil, 89
Fergus Shanahan & John Keohane
- 26** Worms, 93
David Grunkemeier & R Balfour Sartor
- 27** Smoking and nicotine – poison for Crohn’s, potion for colitis? 96
Brian Bressler & A Hillary Steinhart
- 28** Heparin, 100
Ailsa Hart & Stuart Bloom
- 29** Leukocytapheresis: filtering out the facts, 105
Peter Irving & David Rampton
- 30** Appendectomy for ulcerative colitis – a therapeutic option? 108
Richard Makins & Graham Radford-Smith
- 31** Biologic treatments in IBD, 111
Raymond D’Souza & James Lindsay
- 32** Stem cell transplantation for IBD, 116
Paul Fortun & Christopher Hawkey
- 33** Complementary and alternative therapy – the way forward or a step back? 121
Louise Langmead & David Rampton

Part 4 Common Clinical Challenges: Beyond the Text Book

- 34** Functional problems, 125
Eamonn Quigley
- 35** Psychological stress: something to worry about? 129
Joel E D Mawdsley & David Rampton
- 36** Drugs to avoid, 133
Paul Collins & Jonathan Rhodes
- 37** NSAIDs and COX-2 selective agents: cause or cure of pain in IBD? 136
Ingvar Bjarnason & David Scott
- 38** Iron replacement – is it safe and effective? 139
Stefanie Kulnigg & Christoph Gasche
- 39** Hepatitis B and C viruses – how do they affect management of IBD? 142
Graham R Foster & Alick N S Nkhoma
- 40** Pregnancy: what drugs can we use? 146
Thea Thomas & Elspeth Alstead
- 41** How to prevent growth failure in children, 150
Jutta Köglmeier & Nick Croft
- 42** Predicting outcomes in severe UC, 153
Simon Travis

- 43** Refractory proctitis, 156
Anne Ballinger & Richard Makins
- 44** CMV co-infection – does it matter? 159
Daan Hommes
- 45** Treatment of oral Crohn’s disease, 164
Carlo Nunes, Michael Escudier & Jeremy D Sanderson
- 46** Pathophysiologic approach to treatment of diarrhea in Crohn’s disease, 168
Henry J Binder
- 47** Short bowel, 171
Jeremy Nightingale
- 48** Management of internal fistulae, 175
David Rampton
- 49** What is indeterminate colitis? 179
Garret Cullen & Diarmuid O’Donoghue
- 50** Pouches for indeterminate colitis? 182
Laura Hancock & Neil Mortensen
- 51** Colitis-associated cancer: what’s the risk to your patients? 185
Jayne Eaden
- 52** What to do with dysplasia, DALMs, and adenomas, 189
Matt Rutter

Part 5 Managing IBD Outside the Gut

- 53** Pyoderma gangrenosum, 193
Ana Paula Cunha & Fernando Tavela Veloso
- 54** Arthritides – helping the joints without harming the gut, 197
Horace Williams & Tim Orchard
- 55** Prevention and treatment of osteoporosis, 201
Richard Makins & Juliet Compston
- 56** Sclerosing cholangitis – what to do? 205
Sue Cullen & Roger Chapman
- 57** Thromboembolic disease: an under-recognized complication? 209
Peter Irving & Fergus Shanahan
- 58** Pulmonary manifestations: rare but real, 213
Peter Irving

Part 6 Are You Sure it’s IBD?

- 59** Intestinal infections: mimics and precipitants of relapse, 217
Sunil Samuel & Yashwant Mahida
- 60** Microscopic colitis, 222
Debbie Nathan & Peter Gibson

- 61** Diverticular colitis, 226

Linmarie Ludeman & Neil A Shepherd

Part 7 The IBD Service: Time for a Rethink?

- 62** Outpatient services – do doctors still have a role? 229

Mark Kelly & Andrew Robinson

- 63** Shared care: tactical team selection, 233

Reshma C Rakshit & John Mayberry

- 64** Databases – are they worth the bother? 237

Stephen L Grainger

Index, 241

Preface

In early 2004, we instigated at Barts and The London a weekly lunchtime clinical and academic IBD meeting. This is a multidisciplinary meeting, open not only to adult medical consultants and trainee gastroenterologists, but also to others including colorectal surgeons, pediatric gastroenterologists, nurses, the nutrition team, specialist pharmacists, visitors to the Unit, laboratory researchers and medical students: the average attendance is about twenty. During the meetings, we discuss patients we have encountered during the previous week who have presented difficult management problems, as well as practical day-to-day administrative issues. In addition, we decided at the outset of these meetings to ask, in rotation, attending staff each to give a 15-minute presentation on a discrete, current, controversial, important, practical, and often as yet unresolved topic relating to the care of patients with IBD. The subjects are selected by discussion between the group, and one talk is presented each week. The talks have proved extremely popular, both for the audience and the presenter, and it is out of them that the idea for this book arose.

Accordingly, this book contains a series of pithy, we hope enjoyable, sometimes provocative, but generally evidence-based articles on IBD topics which have been selected with a view to covering many of the areas that cause clinicians

difficulties in decision making. As we have deliberately chosen some controversial topics, we should perhaps point out that as editors we do not necessarily agree with all that is written here; if we did the book might prove dull. In line with its origins, some of the chapters of the book have been written in the first instance by younger gastroenterologists, prior to final touches being added by established experts.

We hope that this approach will appeal both to consultant and trainee gastroenterologists, as well as other members of the IBD team. Inevitably, the book will soon become out of date, but we hope that in the interim readers will find that it provides a useful distillation and analysis of a wide range of current management dilemmas. Indeed, we hope that you might read the odd chapter on the bus or in the train, if not in the lavatory or on the beach.

We are very grateful to all our co-authors, almost all of whom delivered their chapters on time and with minimal hassling. We are particularly grateful too to the team at Blackwell's: Alison Brown for her enthusiasm about the project when we first discussed it with her, Fiona Pattison, Mirjana Misina and Linda Bolton for all their editorial work.

LEARNING POINTS**Capsule endoscopy**

- Capsule endoscopy (CE) has a diagnostic yield of 40–70% in patients with suspected small bowel Crohn's disease where other investigations have been normal
- It is not yet clear whether CE provides additional information about the small bowel in patients with known Crohn's disease
- There is an emerging role for CE in differentiating Crohn's disease from indeterminate colitis
- Small bowel follow through (SBFT) is not reliable in predicting capsule retention and the role of the patency capsule is evolving
- SBFT before CE may in due course prove unnecessary in suspected small bowel Crohn's disease

Introduction

In addition to being the section of the gastrointestinal (GI) tract most commonly affected by Crohn's disease, the small bowel (SB) is also the most difficult region to visualize endoscopically. Wireless video capsule endoscopy (CE) is a new technology which, at least in part, overcomes this problem, by allowing complete non-invasive endoscopic imaging of the small bowel.

However, for CE to have a role in the diagnosis and management of small bowel Crohn's disease, it should fulfill several criteria: it should be safe, provide additional diagnostic information and its use should lead to clinically meaningful changes in patient management. In this chapter we discuss the limitations of other small bowel imaging

techniques, the potential uses of CE in relation to Crohn's disease and the evidence to support its use in each scenario.

Limitations of other techniques for imaging small bowel

Imaging of the SB has been previously limited to the radiologic techniques of small bowel follow through (SBFT), enteroclysis (double contrast small bowel examination) and computed tomography (CT) enteroclysis, and the endoscopic techniques of push enteroscopy, double balloon enteroscopy and colonoscopy with ileal intubation.

SBFT is the most common technique used to assess small bowel Crohn's but it is relatively insensitive for subtle mucosal lesions. Enteroclysis and CT enteroclysis are more invasive than SBFT, requiring the passage of a catheter into the duodenum under sedation, and several investigators have found these techniques to be no more sensitive [1]. All three techniques result in significant radiation exposure, limiting the frequency with which they should be performed.

Push enteroscopy can only view the proximal small bowel 15–160 cm beyond the ligament of Treitz and is more invasive and technically difficult than CE. Double balloon enteroscopy is an exciting new technology which has the potential to biopsy and perform therapeutic endoscopy throughout the small bowel. However, the examination is invasive, time consuming and may not examine the entire small bowel even when the procedures are performed per orally and per anally. Visualization of the terminal ileum at colonoscopy is limited both to the distal 10–15 cm of SB and to those patients in whom the terminal ileum can be successfully intubated.

TABLE 1.1 Trials assessing the role of capsule endoscopy in the diagnosis and assessment of Crohn's disease.

Reference	N	Preceding investigation	Yield (%)	Comparator	Yield (%)
<i>Diagnosis of small bowel Crohn's</i>					
Fireman [5]	17	SBFT, EGD, colonoscopy (ileoscopy 6/17)	71	N/A	N/A
Ge [6]	20	SBFT, EGD, colonoscopy	65	N/A	N/A
Herrerias [7]	21	SBFT, EGD, colonoscopy (ileoscopy 17/21)	43	N/A	N/A
Arguelles-Arias [8]	12	SBFT, EGD, colonoscopy	75	N/A	N/A
Liangpunsakul [9]	40	SBFT, EGD, colonoscopy	7.5	CT enteroclysis	0
Eliakim [10]	35	N/A	73	SBFT CT enteroclysis	23 20
Voderholzer [11]	5	SBFT, EGD, colonoscopy	40	CT enteroclysis	40
<i>Assessing disease activity/recurrence</i>					
Buchman [12]	30	N/A	70	SBFT	67
Voderholzer [11]	8	N/A	75	CT enteroclysis	75

Debinski [14]	10	N/A	N/A	CDAI, IBDQ, CRP	N/A
<i>Differentiating SB Crohn's from indeterminate colitis</i>					
Mow [13]	22	N/A	59	Ileoscopy	23
Whitaker [16]	7	Colonoscopy and ileoscopy	29	N/A	

CDAI, Crohn's Disease Activity Index; CRP, C-reactive protein; CT, computed tomography; IBDQ, Inflammatory Bowel Disease Questionnaire; N/A, not available; EGD, esophagogastroduodenoscopy; SBFT, small bowel follow through.

Capsule endoscopy

The Pillcam® capsule endoscope from Given Imaging® was first used in clinical trials in 2000 and was granted Food and Drug Administration (FDA) approval in 2001 (Table 1.1). Since then it has been used in over 200 000 individuals.

Capsule endoscopy images are different from standard endoscopic images. The images are seen through intestinal content without air insufflation. Minimum standard terminology is being developed to allow consistent image description, but more validation with histology is required [2]. In a recent large randomized placebo-controlled trial looking at intestinal inflammation in patients on non-steroidal anti-inflammatory drugs, 7% of those on placebo had small bowel abnormalities [3]; these data raises the question of what constitutes a normal small bowel appearance.

The appearance of Crohn's disease at CE ranges from gross mucosal ulceration and stricturing to subtle mucosal breaks and denuded villi. A CE scoring index has been proposed along the lines of the endoscopic ones, but has not been fully validated [4].

Diagnosis of suspected small bowel Crohn's disease

The majority of trials examining the role of CE in the management of Crohn's disease have studied the diagnostic yield of CE in patients with symptoms and features suggestive of Crohn's who have undergone normal SBFT, esophagogastroduodenoscopy (EGD) and colonoscopy (with attempted ileal intubation in some).

In prospective analyses of this nature, CE appears to provide significant additional information, with a diagnostic

yield ranging between 43% and 71% [5–8]. Furthermore, in all of these studies the positive findings at CE led to a change in management with a resulting improvement in most patients (83–100%), although treatment outcomes are not well reported.

In a retrospective analysis, the diagnostic yield was lower at 7.5% [9]. However, CE compared favorably to enteroclysis and CT enteroclysis, which were reported as normal in all the patients with positive findings at CE. In addition, all the patients responded to instigation of medical therapy.

Other studies have compared the sensitivities of CE with other techniques for diagnosing SB Crohn's disease, by performing the tests in a sequential, blinded manner. In a study comparing sequential SBFT, CT enteroclysis and CE, Eliakim *et al.* [10] found the sensitivities for Crohn's to be 23%, 20%, and 73%, respectively. Volderholzer *et al.* [11] found CE made a new diagnosis of SB Crohn's in two of five patients with unexplained diarrhea, both of whom had normal prior CT enteroclysis.

In summary, current evidence suggests that CE has a diagnostic yield of 40–70% in patients with symptoms suggestive of Crohn's disease where SBFT, OGD and colonoscopy with attempted ileal intubation have been normal. Direct comparison of diagnostic yield with enteroclysis and CT enteroclysis favors CE. The new diagnosis of Crohn's by CE has led to the institution of a beneficial new treatment regimen in most patients.

Assessment of disease activity and recurrence

Few trials have examined whether CE is useful in assessing the SB in patients with known Crohn's. Buchman *et al.* [12] found SBFT and CE to have similar diagnostic yields at 66% and 70% in patients with suspected disease recurrence while Volderholzer *et al.* [11] found CE and CT enteroclysis each to have a diagnostic yield of 75%. Mow *et al.* [13] suggested three or more ulcers were diagnostic of Crohn's; they found CE was diagnostic in 40% and suspicious for Crohn's in 30% of patients, but did not make additional diagnoses compared with ileoscopy.

In a study to assess its potential for detection of early postoperative recurrence of Crohn's, the diagnostic yield of CE was 75% in patients with previous SB resection and suspected recurrence who had had normal SBFT, OGD, colonoscopy, and push enteroscopy [14].

Only one study has examined the role of CE in assessing

response to therapy. In this, improvements in mucosal appearance at CE were seen in 8/10 patients given infliximab [15]; these correlated with changes in Crohn's Disease Activity Index (CDAI), Inflammatory Bowel Disease Questionnaire (IBDQ) scores and C-reactive protein (CRP).

In summary, CE appears to detect recurrent small bowel Crohn's disease with a diagnostic yield of approximately 70%. However, it is not clear whether CE adds usefully to the information provided by conventional imaging techniques in this setting, nor do we yet know whether findings at CE lead to beneficial changes in management. It is therefore too early to define the role for CE in the assessment of response to therapy and of postoperative disease recurrence.

Differentiating Crohn's disease from indeterminate colitis

In a retrospective study, CE detected SB lesions suspicious of Crohn's in 13/22 patients with a previous diagnosis of indeterminate colitis and in five led to a change in management [13]. There was, however, no comparison made to other conventional imaging techniques or to the use of antibodies to *Saccharomyces cerevisiae*/antineutrophil cytoplasmic antibody (ASCA/ANCA) serology. In a second study, CE identified lesions characteristic of CD in 2/7 patients with a diagnosis of indeterminate colitis and ongoing pain and/or diarrhea, all of whom had already undergone non-diagnostic ileoscopy [16].

Is capsule endoscopy safe in Crohn's disease?

In all of the studies discussed above, SBFT was performed prior to CE and patients with significant stricturing were excluded from CE. CE retention occurred in 1/71 (1.4%) patients with suspected Crohn's, and in 4/80 (5%) patients with known Crohn's disease. In the trials of suspected SB Crohn's, very few patients were excluded because of abnormal radiology and radiology did not reliably prevent retention; SBFT may not therefore be required prior to CE in this setting.

Concerns regarding capsule endoscope retention have led to the development of the Patency capsule. This has the same dimensions as the Pillcam® capsule but contains only a simple tracer and is designed to disintegrate in the GI tract 40–100 hours after ingestion. In a multicenter study, the Patency capsule was passed intact in 41/80 patients with

known small bowel strictures of whom 33 then underwent conventional CE. There were no cases of capsule retention although some patients did report abdominal pain [17].

Tolerability and capsule failure

In all the studies discussed, with the exception of patients in whom it was retained, the capsule was easily swallowed and well tolerated. Although there are no comparative preference data in these studies, in a different analysis 49/50 patients preferred CE to push enteroscopy [18].

In those studies where the data were given, the capsule failed to reach the colon before the end of its 8 hour battery life in 25/132 cases (failure rate 19%). However, in most cases, an incomplete examination did not affect diagnostic efficacy.

Conclusions

Although the number of studies is small, current evidence suggests that there is a role for CE in the diagnosis of suspected SB Crohn's disease. However, more work is required to determine the clinical significance of the more subtle mucosal lesions and whether CE can safely be performed without prior radiology. A role for CE in assessing patients with indeterminate colitis is slowly emerging but its role in assessing disease recurrence is less clear. The Patency capsule is likely to prove useful in patients with known or suspected small bowel strictures.

Investigating IBD in the 21st Century

2

Pathology reports – pitfalls for the unwary*

WILFRED WEINSTEIN

LEARNING POINTS

Pathology reports

- Communication between pathologist and endoscopist is crucial and must be two-way
 - Do not force the pathologist to make unrealistic diagnoses or rush to judgment
 - Encourage the pathologist to avoid using hackneyed, vague, misleading, or non-actionable diagnoses
 - The endoscopist's ego strength should be sufficient to allow the pathologist to complain about poor quality biopsies, lack of clinical information, or unrealistic expectations
 - Educate each other! Send references of clinicopathologic importance in IBD to the pathologist
- Ask questions that reflect *what is possible* to determine from biopsy pathology
- Include clinical information relevant to the differential diagnosis

Introduction

Pitfalls in pathology reports are a product of misunderstanding or miscommunication in regards to the role of biopsy in the differential diagnosis of UC and Crohn's disease. Colonic biopsy has a limited role *by itself* in the initial

evaluation, differential diagnosis, and subsequent management of inflammatory bowel disorders. However, when taken together with the history, endoscopic findings, and clinical course it may significantly help to make the case for one type of IBD rather than another [1,2].

Pitfalls occur with the too-oft practice of not providing the pathologist with an adequate history and endoscopic description, or with unrealistic expectations of what biopsy can do in management. The pathologist may not have sufficient information about the clinical manifestations and therapy of the disorders. This results in failure to be descriptive alone, when the endoscopist pressures naively or prematurely for a single diagnosis. Compounding the pitfalls is the "silence of the pathologists" who put up with no historical or endoscopic information, inadequate biopsies, and unrealistic expectations. They rarely communicate these deficiencies to the clinician [3].

Special problems and how to minimize the risk of errors

Ulcerative proctitis

A biopsy is taken within a 10-cm segment of apparent diffuse inflammation in the rectum and the endoscopist asks the pathologist to "rule out ulcerative proctitis." The pathologist should never make this diagnosis unless a biopsy taken approximately 10 cm upstream is normal; that

*UNWARY: adj: not alert to danger or deception; "seduce the unwary reader into easy acquiescence" [*The American Heritage® Dictionary of the English Language*, 4th edn, Copyright © 2000 by Houghton Mifflin Company]. Not alert: easily fooled or surprised. Heedless, gullible [from dictionary.com].

rules out proctosigmoiditis. If the proximal biopsy is normal then one can have the “ulcerative proctitis talk” with the patient, indicating that 90% of the time the disorder does not migrate proximally [4]. If the endoscopist does not consider other possible relevant causes of ulcerative proctitis when biopsies are taken, an erroneous report is inevitable; as in mucosal prolapse due to solitary rectal ulcer syndrome (SRUS), mucosal trauma from digital removal of stool, anal intercourse, sexually transmitted disease [5], and ischemic proctitis, especially after aortoiliac bypass surgery.

Questions for the pathologist and avoiding unrealistic expectations

(Table 2.1)

“Rule out Crohn’s disease”

This guarantees that the pathologic diagnosis will be *compatible with Crohn’s disease* because almost any histologic findings are compatible with Crohn’s disease. The solution is for the clinician to ask the pathologist if there are findings of focal inflammation in diffusely abnormal mucosa

TABLE 2.1 Lesion descriptions, relevant medications, history, and questions for the pathologist. (After Weinstein [3])

Lesion description

Simple language for mucosal abnormalities: thick folds rather than hypertrophic; define friability if used, i.e. single pass petechiae or bleeding; or spontaneous petechiae or oozing. Describe what was seen rather than an interpretive term such as colitis

Key drugs

Type of preparation (enemas or oral)
Current IBD treatment
Any other immunosuppressives (e.g. after transplantation)
Chemotherapy or radiotherapy (and when last treatment with same)
Current or recent NSAIDs, cocaine, methamphetamine
Current or recent antibiotics

History

Brief usually suffices
Duration of diarrhea, bloody or non-bloody
Risk factors for other disorders (see section on ulcerative proctitis)
Underlying cardiac or vascular disease if present

Question for the pathologist

Be as specific as possible (see text)

NSAIDs, non-steroidal anti-inflammatory drugs.

endoscopically and if there are non-crypt cell granulomas (because granulomas next to partially degraded crypts are a feature of UC). Neither finding clinches the diagnosis of Crohn’s but the question alerts the pathologist that you are looking for more solid evidence than any small collection of inflammatory cells.

“Rule out UC in a patient with diffusely abnormal mucosa”

My favorite question in apparent UC endoscopically is in two parts:

- 1 “It looks like UC but are there features to suggest something else?” This alerts the pathologist to look for disorders that can mimic UC, such as infectious colitis (acute self-limited) or multifocal non-crypt associated granulomas that would suggest Crohn’s disease or ischemic bowel. In endoscopically classic UC, biopsies help most when the findings do not fit.
- 2 “Are there classic signs of underlying UC?” This refers to crypt branching and subcryptal inflammatory infiltrates.

“Is it UC or Crohn’s disease?”

Settings where that distinction is difficult to impossible in a single series of biopsies at any point in time include [2]: fulminant colitis, treated IBD, mild IBD, and new onset UC in children. A meeting of the two solitudes (clinician and pathologist) will: (i) inform the clinician about these special situations; and (ii) empower the pathologist to avoid being a collaborator in providing a definitive diagnosis when that is not possible. Fulminant or highly severe UC can be transmural and resemble Crohn’s disease. In treated UC, mild UC, and in childhood UC at presentation (even with moderate to severe symptoms), the rectum may be spared and the inflammation more severe in proximal than distal parts of the colon [2,6]. Thus, Crohn’s might be the erroneous diagnosis based upon patchiness and rectal sparing. Overall, the best time to make the distinction between UC and Crohn’s disease in adults is in the untreated state when there are active but not fulminant symptoms.

The rush to judgment

The endoscopist should not rush to judgment, and furthermore not press the pathologist to collaborate in a rush to judgment. In patients with shorter term histories of diarrhea it may be most prudent to simply call it colitis, leave open the possibility of a self-limited disease, and treat with the usual drugs. The most common error we make is the knee

jerk label of Crohn's for any focal endoscopic involvement. Drug-induced colitis (non-steroidal anti-inflammatory drugs [NSAIDs], cocaine, methamphetamines) might be responsible for a Crohn-like or an ischemic picture [7]. Aphthous lesions from PhosphoSoda preparations occur commonly in the left colon. Ischemic colitis appearances on biopsy may be produced by infections, not just the classic *Escherichia coli* OH:157, but also others such as *Salmonella*, *Shigella*, *Clostridium difficile*, and *Campylobacter jejuni*.

Biopsies taken near diverticula to look for IBD

But the endoscopist does not tell the pathologist about the diverticulosis. A bona fide segmental colitis, only in an area of diverticula, may represent diverticular colitis and not some other focal disease such as Crohn's disease [8] (see Chapter 61).

Colitis in the immunocompromised patient

In patients with common variable immunodeficiency, undergoing chemotherapy or radiotherapy, or with human immunodeficiency virus (HIV) with low CD4 counts, and after transplantation, the main role of the endoscopist is to rule out infectious causes or endogenous changes such as chemotherapy or radiation change. UC or Crohn's disease are difficult if not impossible diagnoses to make with assurance in these settings.

The pathologist's vague, meaningless, or non-actionable terminology¹

Mild chronic inflammation is the greatest pandemic affecting the gastrointestinal tract. Usually these are cases with normal mucosa. Mild inflammation is present in the right colon in health, accompanied by scattered eosinophils and crypt mucus depletion, but not cryptitis. If the pathologist is not aware of this regional difference or if the endoscopist mixes right and left sided colonic biopsies into one fixative bottle, then irrelevant diagnoses may result for the unwary clinician.

Non-actionable terms unfortunately still abound. **Moderate dysplasia** in the colon is not a standard dysplasia grade, and there is no published action plan for it. **Unqualified atypia** may lead to panic and the term should not be used

unless accompanied by the adjective of **regenerative-type atypia**.

Clinical correlation recommended. What does this mean? Many pathologists use this as a covert term for "I'm concerned" or "I don't know what's going on histologically" to fit the clinical and/or endoscopic picture. Either sentiment is permissible. The solution is to remove the phrase and phone the clinician, or transmit any special concern in the pathology report.

Indeterminate colitis. This term should not be used in biopsy reports, ever. An elegant review is available for those of us who are perplexed by the diagnosis of indeterminate colitis [2].

Conclusion

Histology taken at ileocolonoscopy plays a central part in the diagnosis and management of IBD. Frequent and specific communication between clinician and pathologist is the best way to minimize the risk of erroneous conclusions being reached.

Investigating IBD in the 21st Century

3

Non-invasive diagnosis and assessment

ALEX J DI MAMBRO, ANA TERLEVICH & CHRIS PROBERT

LEARNING POINTS

Non-invasive diagnosis and assessment

- C-reactive protein remains an important diagnostic and monitoring tool
- Raised fecal calprotectin correlates strongly with disease activity, has been used as a screening test for IBD and may predict relapse
- The combination of perinuclear antineutrophil cytoplasmic antibody (pANCA) and antibodies to *Saccharomyces cerevisiae* (ASCA) may help differentiate ulcerative colitis from Crohn's disease, especially in children
- In the right hands, abdominal ultrasound identifies active IBD in the terminal ileum and colon
- Analysis of fecal volatiles and genetic mutations may in the future alter the way we diagnose, monitor and treat IBD.

Introduction

Non-invasive assessment of IBD is desirable from the patient's point of view, as it is relatively painless and has few complications. However, it is also desirable from the clinical perspective: patients with chronic disease should not be exposed repeatedly to ionizing radiation, nor to endoscopic investigations, because of the potential risks from such procedures. In addition, in some parts of the world, endoscopy services are becoming over-stretched due, for example, to demands for colorectal cancer screening. In this synopsis, we discuss non-invasive methods for diagnosing and assessing IBD.

C-reactive protein

C-reactive protein (CRP), principally produced by hepatocytes, is part of the acute phase response. It has a short half-life and is therefore a useful marker to detect and monitor disease activity in Crohn's disease [1]. A raised CRP is, of course, non-specific, but, like a raised platelet count, can point to the possibility of IBD in patients presenting to the clinic with diarrhea and/or abdominal pain. In UC the acute phase response of CRP is, for unknown reasons, only modest, and CRP is not as good a marker of disease activity except in severe relapses, when a CRP >45 mg/L during treatment indicates a high risk of colectomy (see Chapter 42) [2]. Interestingly, recent trials of biologic agents in patients with Crohn's disease have found that those patients with raised CRP tend to respond better than those without (see Chapters 23, 31).

Plasma viscosity

Plasma viscosity is sometimes used alone, or in conjunction with CRP, to assess disease activity in IBD but is also non-specific. It has been shown to correlate well with CRP in both UC and Crohn's disease; however, it has a low sensitivity for detecting active Crohn's disease, being within the normal laboratory range in 48% of those with active disease [3].

Calprotectin

Calprotectin is a calcium-binding protein secreted predominantly by neutrophils. Elevated fecal calprotectin levels

are found in many inflammatory diseases of the intestine [4] and have been proposed as a way of deciding which patients with diarrhea and abdominal pain need further investigation for IBD. Fecal calprotectin levels correlate strongly with IBD activity and may be used to predict relapse [5].

Serology – pANCA and ASCA

Recent papers have shown a strong association between certain antibodies and IBD.

Perinuclear antineutrophil cytoplasmic antibody (pANCA) is found in patients with rheumatoid arthritis, systemic lupus erythematosus, microscopic polyangitis, and also in IBD. The prevalence of pANCA is increased in patients with UC (30–80%) compared with healthy controls. In comparison, pANCA is found less commonly in patients with Crohn's disease (0–20%). In UC, pANCA appears independent of disease extent and activity; however, in Crohn's disease its presence has been associated with UC-like features [6]. pANCA can be subdivided according to which perinuclear antigen antibodies are directed against. In patients with UC, the antigen may be histone 1, but antibodies are not directed against proteinase 3, myeloperoxidase, elastase, lysozyme, or cathepsin G [7].

The prevalences of IgG and IgA antibodies to *Saccharomyces cerevisiae* (ASCAs) are increased in patients with Crohn's disease compared with controls and range from 35–76% [8]. Patients who are ASCA-positive are more likely to have disease of the ileum, or ileum and colon, than patients who are ASCA-negative. Furthermore, ASCA-positive patients have also been shown to be more likely to require ileocecal resection [9].

Combining pANCA with ASCA increases specificity. For example, in UC, pANCA alone has a sensitivity and specificity of 65% and 85%, respectively; however, when combined with a negative ASCA, the sensitivity is 57% and the specificity 97% [10]. The positive predictive value (PPV) is therefore increased from 74% to 92% when the antibodies are combined.

Combined pANCA and ASCA has also been used to increase diagnostic accuracy in categorizing indeterminate colitis. One recent study showed that pANCA-positive and ASCA-negative patients with indeterminate colitis often progressed to a diagnosis of UC (PPV 64%), whereas those who were pANCA-negative and ASCA-positive were more likely to have CD (PPV 80%) [11].

Although pANCA alone is unlikely to provide the basis for a non-invasive screening test for IBD, it appears that in combination with ASCA it may have some adjuvant uses in differentiating Crohn's disease from UC, in categorizing indeterminate colitis, and possibly in determining disease pattern in Crohn's disease.

Recently, two new potential marker antibodies have been described: OmpC and I2. The low sensitivity of the antibodies to detect either Crohn's disease or ulcerative colitis means they are unlikely to have a diagnostic role [12], but they may be useful in screening for a fistulizing/stenotic phenotype with Crohn's disease as they are strongly associated with this pattern in children ($p < 0.006$ and < 0.003 for OmpC and I2, respectively [13]).

Abdominal ultrasound

Abdominal ultrasound offers a simple, accessible, and non-invasive method of detecting and monitoring IBD (in particular Crohn's disease) and yet, at least in the UK, it is under-utilized. It has an overall accuracy of 89% in identifying active terminal ileal and colonic Crohn's disease (see Chapter 4) [14]. Doppler sonography, with or without contrast, is a newer, non-invasive method of assessing the hyperdynamic splanchnic and mesenteric blood flow that occurs in active inflammation. It can detect early mucosal and transmural inflammatory lesions. Furthermore, repeated quantification of mesenteric blood flow is claimed to enable the prediction of relapse at 6 months after steroid-induced remission [15]. (The role of magnetic resonance imaging [MRI] is discussed in Chapter 4.)

Analysis of fecal volatiles

Some patients with IBD have observed that the gas they emit per rectum during periods of disease activity smells different to that emitted when their disease is quiescent. Recently, we have investigated the composition of gas emitted from stool samples to explore this observation further and have found that the volatile compounds of such gas are different from those found in healthy volunteers. Furthermore, the gas produced by such stool samples can be used to distinguish between UC and Crohn's disease. This observation may lead to a novel diagnostic test.

However, the technique is still under evaluation and these results need to be reproduced in larger series before its usefulness for non-invasive diagnosis or monitoring of IBD can be determined.

Genetic mutations and IBD

The first gene to be identified as a risk factor for Crohn's disease is the *NOD2/CARD15* gene on chromosome 16 (see Chapter 24). Mutations of the gene are significantly more common in patients with Crohn's disease than in healthy controls. However, although the odds ratio is impressive, the genetic mutations are present in fewer than half of the patients studied [16,17]. At present, screening for these genes or other mutations plays no part in the diagnosis or monitoring of IBD [18].

Conclusions

At present, CRP and plasma viscosity remain the only widely available means of non-invasive monitoring of IBD. Fecal calprotectin looks promising as a diagnostic pointer towards IBD; it has the advantage of being a test of luminal disease and is therefore unlikely to be influenced by extra-intestinal disease processes. pANCA and ASCA may have a role in distinguishing Crohn's disease from UC and, potentially, IBD from other gastrointestinal disorders. Ultrasound warrants further investigation as a non-invasive technique for both diagnosing and monitoring Crohn's disease. Analysis of fecal volatiles is still at an early stage of development but also appears promising. Genetic screening is unlikely, in the foreseeable future, to be used to make a diagnosis of IBD.

LEARNING POINTS**Imaging pelvic Crohn's disease**

- Perianal fistulae associated with Crohn's disease are often complex and tend to recur if the full extent is under-diagnosed at presentation
- Magnetic resonance imaging (MRI) and endoanal ultrasound (with or without hydrogen peroxide) are the investigations of choice
- MRI has superior contrast resolution and can identify deep extensions of complex perianal disease

Introduction

Pelvic Crohn's disease encompasses a spectrum of conditions including perianal skin tags, fissures, ulcers, and perianal abscesses and fistulae. Six to 34% of patients develop anal fistulae [1] and the diagnosis and treatment of these fistulae can be particularly challenging.

Although simple perianal fistulae can be identified at examination under anesthesia (EUA) and then treated successfully without the need for diagnostic imaging [2], fistulae associated with Crohn's disease are frequently complex with secondary extensions and ramifications. Failure to appreciate the complexity of such fistulae at EUA could result in incomplete treatment and may be responsible for the high rate of recurrence [3].

Several imaging modalities have been employed to

delineate fistulous tracks, each with advantages and limitations. Fistulae should be classified as described by Parks *et al.* [4] to provide the surgeon with a roadmap which should minimize both operative trauma to the anal sphincters and subsequent recurrence.

Imaging

Contrast fistulography has historically been used to delineate fistula anatomy. This involves cannulating the external opening and injecting water-soluble contrast material under X-ray control. However, the technique has been shown to be unreliable, with an accuracy of only 16% [5]. It gives little information about the immediate anatomic relations especially to the sphincter mechanism and levator plate. The complete extent of complex fistulae and deep abscesses may not be identified if they fail to fill with contrast.

Although valuable in the overall assessment of complex transmural Crohn's disease, **computed tomography (CT)** has major limitations in the evaluation of perianal disease. The density of the anal sphincter, levator muscle, active fistulae, and fibrotic tracks on CT images are very similar, so that it is difficult to differentiate between them unless the fistula has been outlined by air or contrast [6].

CT has a role in the guidance of drainage of deep pelvic abscesses. It is widely available and allows a safe approach for drainage in an area where multiple intervening structures must be avoided. A transabdominal or transgluteal approach may be used [7].

Anal endosonography uses a high-frequency endoanal probe (typically 10 MHz) to evaluate sphincter anatomy
