### Contents

Preface xvi

List of Contributors xviii

Volume 1

### 1 Nanomaterials – An Introduction 1

- C. N. R. Rao, A. Müller, and A. K. Cheetham
- 1.1 Size Effects 3
- 1.2 Synthesis and Assembly 4
- 1.3 Techniques 5
- 1.4 Applications and Technology Development 8
- 1.5 Nanoelectronics 8
- 1.6 Other Aspects 9
- 1.7 Concluding Remarks 11 Bibliography 11

### 2 Strategies for the Scalable Synthesis of Quantum Dots and Related Nanodimensional Materials 12

P. O'Brien and N. Pickett

- 2.1 Introduction 12
- 2.2 Defining Nanodimensional Materials 13
- 2.3 Potential Uses for Nanodimensional Materials 15
- 2.4 The General Methods Available for the Synthesis of Nanodimensional Materials *17*

v

- 2.4.1 Precipitative Methods 19
- 2.4.2 Reactive Methods in High Boiling Point Solvents 20
- 2.4.3 Hydrothermal and Solvothermal Methods 22
- 2.4.4 Gas-Phase Synthesis of Semiconductor Nanoparticles 23
- 2.4.5 Synthesis in a Structured Medium 24
- 2.5 The Suitability of Such Methods for Scaling 25
- 2.6 Conclusions and Perspectives on the Future 26

### Preface

Nanomaterials, characterized by at least one dimension in the nanometer range, can be considered to constitute a bridge between single molecules and infinite bulk systems. Besides individual nanostructures involving clusters, nanoparticles, quantum dots, nanowires and nanotubes, collections of these nanostructures in the form of arrays and superlattices are of vital interest to the science and technology of nanomaterials. The structure and properties of nanomaterials differ significantly from those of atoms and molecules as well as those of bulk materials. Synthesis, structure, energetics, response, dynamics and a variety of other properties and related applications form the theme of the emerging area of nanoscience, and there is a large chemical component in each of these aspects. Chemistry plays a particularly important role in the synthesis and characterization of nanobuilding units such as nanocrystals of metals, oxides and semiconductors, nanoparticles and composites involving ceramics, nanotubes of carbon and inorganics, nanowires of various materials and polymers involving dendrimers and block copolymers. Assembling these units into arrays also involves chemistry. In addition, new chemistry making use of these nanounits is making great progress. Electrochemistry and photochemistry using nanoparticles and nanowires, and nanocatalysis are examples of such new chemistry. Nanoporous solids have been attracting increasing attention in the last few years. Although the area of nanoscience is young, it seems likely that new devices and technologies will emerge in the near future. This book is intended to bring together the various experimental aspects of nanoscience of interest to chemists and to show how the subject works.

The book starts with a brief introduction to nanomaterials followed by chapters dealing with the synthesis, structure and properties of various types of nanostructures. There are chapters devoted to oxomolybdates, porous silicon, polymers, electrochemistry, photochemistry, nanoporous solids and nanocatalysis. Nanomanipulation and lithography are covered in a separate chapter. In our attempt to make each contribution complete in itself, there is some unavoidable overlap amongst the chapters. Some chapters cover entire areas, while others expound on a single material or a technique. Our gratitude goes to S. Roy for his valuable support in preparing the index manuscript.

We trust that beginners, teachers and practitioners of the subject will find the

# Preface xvii

book useful and instructive. The book could profitably be used as the basis of a university course in the subject.

## 1 Nanomaterials – An Introduction

C. N. R. Rao, A. Müller, and A. K. Cheetham

The term nanotechnology is employed to describe the creation and exploitation of materials with structural features in between those of atoms and bulk materials, with at least one dimension in the nanometer range  $(1 \text{ nm} = 10^{-9} \text{ m})$ . In Table 1.1, we list typical nanomaterials of different dimensions. Properties of materials of nanometric dimensions are significantly different from those of atoms as well as those of bulk materials. Suitable control of the properties of nanometer-scale structures can lead to new science as well as new devices and technologies. The underlying theme of nanotechnology is miniaturization. The importance of nanotechnology was pointed out by Feynman as early as 1959, in his often-cited lecture entitled "There is plenty of room at the bottom". The challenge is to beat Moore's law, according to which the size of microelectronic devices shrinks by half every four years. This implies that by 2020, the size will be in the nm scale and we should be able to accommodate 1000 CDs in a wristwatch, as predicted by Whitesides.

1

There has been an explosive growth of nanoscience and technology in the last few years, primarily because of the availability of new strategies for the synthesis of nanomaterials and new tools for characterization and manipulation (Table 1.2). There are many examples to demonstrate the current achievements and paradigm shifts in this area. Scanning tunneling microscope (STM) images of quantum dots (e.g. germanium pyramid on a silicon surface) and of the quantum corral of 48 Fe atoms placed in a circle of 7.3 nm radius being familiar ones (Figure 1.1). Several methods of synthesizing nanoparticles, nanowires and nanotubes, and their assemblies, have been discovered. Thus, nanotubes and nanowires of a variety of inorganic materials have been discovered, besides those of carbon. Ordered arrays or superlattices of nanocrystals of metals and semiconductors have been prepared. Nanostructured polymers formed by the ordered self-assembly of triblock copolymers and nanostructured high-strength materials are other examples.

Besides the established techniques of electron microscopy, diffraction methods and spectroscopic tools, scanning probe microscopies have provided powerful means for studying nanostructures. Novel methods of fabrication of patterned nanostructures as well as new device and fabrication concepts are constantly being

#### 2 1 Nanomaterials – An Introduction

	Size (approx.)	Materials
Nanocrystals and clusters (quantum dots)	diam. 1–10 nm	Metals, semiconductors, magnetic materials
Other nanoparticles	diam. 1–100 nm	Ceramic oxides
Nanowires	diam. 1–100 nm	Metals, semiconductors, oxides, sulfides, nitrides
Nanotubes	diam. 1–100 nm	Carbon, layered metal chalcogenides
Nanoporous solids	pore diam. 0.5–10 nm	Zeolites, phosphates etc.
2-Dimensional arrays (of nano particles)	several nm2–µm2	Metals, semiconductors, magnetic materials
Surfaces and thin films	thickness 1–1000 nm	A variety of materials
3-Dimensional structures (superlattices)	Several nm in the three dimensions	Metals, semiconductors, magnetic materials

Tab. 1.1.	Examples	of nanoma	aterials.
-----------	----------	-----------	-----------

discovered. Nanostructures are also ideal for computer simulation and modelling, their size being sufficiently small to accommodate considerable rigor in treatment. In computations related to nanomaterials, one deals with a spatial scaling from 1 Å to 1  $\mu$ m and a temporal scaling from 1 fs to 1 s, the limit of accuracy going beyond 1 kcal mol<sup>-1</sup>. Prototype circuits involving nanoparticles and nanotubes for nanoelectronic devices have been fabricated. Quantum computing has made a beginning and appropriate quantum algorithms are being developed.

Let us not forget that not everything in nanoscience is new. Many existing technologies employ nanoscale processes, catalysis and photography being well-known examples. Our capability to synthesize, organize and tailor-make materials at the nanoscale is, however, of recent origin. Novel chemistry has been generated by employing nanoparticles, nanowires and other nanostructures. This includes electrochemical, photochemical, catalytic and other aspects. The immediate objectives of the science and technology of nanomaterials are: (i) to fully master the synthesis of isolated nanostructures (building blocks) and their assemblies with the desired properties, (ii) to explore and establish nanodevice concepts and systems architectures, (iii) to generate new classes of high performance materials, (iv) to connect

Scale (approx.)	Synthetic Method	Structural Tool	Theory and simulation
0.1 to ~10 nm	Covalent synthesis	Vibrational spectroscopy NMR Diffraction methods	Electronic structure
${<}1$ to ${\sim}100~\text{nm}$	Techniques of self-assembly	Scanning probe microscopies	Molecular dynamics and mechanics
100 nm to ${\sim}1~\mu\text{m}$	Processing, modifications	SEM, TEM	Coarse-grained models etc.

Tab. 1.2. Methods of synthesis and investigation of nanomaterials.

nanoscience to molecular electronics and biology, and (v) to improve known tools while discovering better tools of investigation of nanostructures.

#### 1.1 Size Effects

Size effects constitute a fascinating aspect of nanomaterials. The effects determined by size pertain to the evolution of structural, thermodynamic, electronic, spectroscopic, electromagnetic and chemical features of these finite systems with increasing size. Size effects can be classified into two types, one dealing with specific size effects (e.g. magic numbers of atoms in metal clusters, quantum mechanical effects at small sizes) and the other involving size-scaling applicable to relatively larger nanostructures. The former includes the appearance of new features of metal and semiconductor nanocrystals differ from those of bulk materials and isolated atoms. In Figure 1.3, we show the size-dependence of the average energy level spacing of sodium in terms of the Kubo gap ( $E_F/N$ ) in K. In this figure, we also show the effective percentage of surface atoms as a function of particle diameter. Note that at small size, we have a high percentage of surface atoms.

Size affects the structure of nanoparticles of materials such as CdS and CdSe, and also their properties such as the melting point and the electronic absorption spectra. In Figures 1.4 and 1.5, we show such size effects graphically. It should be noted that even metals show nonmetallic band gaps when the diameter of the nanocrystals is in the 1–2 nm range. Hg clusters show a nonmetallic band gap which shrinks with increase in cluster size. It appears that around 300 atoms are necessary to close the gap. It is also noteworthy that metal particles of 1–2 nm diameter also exhibit unexpected catalytic activity, as exemplified by nanocatalysis by gold particles.

4 1 Nanomaterials – An Introduction

#### Density of states

**Fig. 1.2.** Density of states for metal and semiconductor nanocrystals compared to those of the bulk and of isolated atoms [from C. N. R. Rao, G. U. Kulkarni, P. J. Thomas, P. P. Edwards, *Chem-Euro J.*, **2002**, *8*, 29.].

#### 1.2 Synthesis and Assembly

The synthesis of nanomaterials and assembling the nanostructures into ordered arrays to render them functional and operational are crucial aspects of nanoscience. The materials/structures include nanoparticles, nanowires, nanotubes,

Particle diameter (D / Å)

**Fig. 1.3.** A plot of the average electronic energy level spacing (Kubo gap,  $\delta$ ) of sodium as a function of the particle diameter. Also shown is the percentage of sodium atoms at

the surface as a function of particle diameter [From P. P. Edwards, R. L. Johnston and C. N. R. Rao, in *Metal Clusters in Chemistry*, ed. P. Braunstein et al., John Wiley, 1998.].

nanocapsules, nanostructured alloys and polymers, nanoporous solids and DNA chips. What is also noteworthy is that chemists have synthesized molecular entities of nanometric dimensions. In Figure 1.6, we show a two-dimensional crystalline array of thiolized metal nanocrystals to illustrate self-assembly.

#### 1.3 Techniques

The emerging nanoworld encompasses entirely new and novel means of investigating structures and systems, besides exploiting the well known microscopic, diffraction and spectroscopic methods. Species as small as single atoms and molecules are manipulated and exploited as switches. Computer-controlled scanning probe microscopy enables a real-time, hands-on nanostructure manipulation. Nanomanipulators have also been designed to operate in scanning and transmission electron microscopes. A nanomanipulator gives virtual telepresence on the

Radius(Å) Fig. 1.4. (a) Size dependence of the melting temperature of CdS nanocrystals. (b) Size dependence of the pressure-induced wurtzite-rock salt transformation in CdSe nanocrystals [from A. P. Alivisatos, J. Phys. Chem., 1996, 100, 13226.].

surface, with a scale factor of a million to one. Optical tweezers provide another approach to holding and moving nanometer structures, a capability especially useful in investigating the dynamics of molecules and particles. Questions such as, how does a polymer move, generate force, respond to an applied force and unfold, can be answered by the use of optical tweezers. It is noteworthy that the positioning of nanoparticles accurately and reliably on a surface by using the tip of an atomic force microscope as a robot has already been accomplished. Large-scale operations requiring parallel tip arrays are being explored in several laboratories.

#### 1.4 Applications and Technology Development

Some of the important applications and technologies based on nanomaterials are the following: (i) Production of nanopowders of ceramics and other materials, (ii) nanocomposites, (iii) development of nanolectrochemical systems (NEMS), (iv) Applications of nanotubes for hydrogen storage and other purposes, (v) DNA chips and chips for chemical/biochemical assays, (vi) gene targeting/drug targeting and (vii) nanoelectronics and nanodevices. The last one, which is probably the most challenging area, includes new lasers, nanosensors, nanocomputers (based on nanotubes and other materials), defect-free electronics for future molecular computers, resonant tunneling devices, spintronics and the linking of biological motors with inorganic nanodevices.

#### 1.5

#### Nanoelectronics

The multidisciplinary area of nanoelectronics has two objectives: (i) utilization of a single nanostructure (e.g. nanocrystal, quantum dot, nanotube) for processing electrical, optical or chemical signals, and (ii) utilization of nanostructured materials involving assemblies of nanostructures for electronic, optoelectronic, chemical and other applications. While it is often difficult to make distinctions between the two, the first category is specifically intended to obtain single-electron devices and the second category is for the purpose of miniaturization in information storage
